## 1. Introduction

For compliance with the requirements of the luminaire standard IEC/EN 60598, no part of the luminaire shall attain a temperature which would impair safety when the luminaire is operated at its rated ambient temperature  $t_a$ .

For the controlgear the temperature limit is defined as the rated maximum temperature of the case of the controlgear ( $t_c$ ) measured at the given reference point marked by the device manufacturer.

This technical information explains

- \_ the meaning of the  $t_a$  and  $t_c$  temperature
- \_ when and how to use  $t_a$  and  $t_c$
- \_ the relevance of  $t_a$  and  $t_c$  for the thermal performance and lifetime of the controlgear

## 2. Definitions for $t_a$ and $t_c$

### **Rated maximum ambient temperature $t_a$ :**

The controlgear standard IEC/EN 61347 contains no definition of  $t_a$  and its measurement for luminaire inbuilt controlgear.

For independent controlgear the luminaire standard applies.

The luminaire standard requires the marking of the rated maximum ambient temperature  $t_a$ , if other than 25 °C.

### **Rated maximum case temperature $t_c$ :**

The definition according to the lamp controlgear standard IEC/EN 61347 is:

"highest permissible temperature which may occur on the outer surface (at the indicated place, if marked) under normal conditions and at the rated voltage or the maximum of the rated voltage range"

## 3. Difference between $t_a$ and $t_c$

- \_  $t_a$  = ambient temperature:  
The temperature range of the air surrounding the electronic controlgear declared by the manufacturer.
- \_  $t_c$  = case temperature:  
The temperature of a reference point on the controlgear housing.

## 4. Importance of $t_a$ and $t_c$

The ambient temperature  $t_a$  has direct influence on the lifetime of electronic components.

If the ambient temperature  $t_a$  is too high, the device cannot emit enough heat to the environment. This can result in so-called hotspots (points where the temperature concentrates). Hotspots in the air close to the components can lead to premature aging and failure of the devices.

The lifetime of a controlgear is based on its ambient temperature.

The case temperature  $t_c$  is the highest permissible temperature which may occur at the  $t_c$  point on the controlgear housing for safe operation.

## 5. Need for two different temperature values

The ambient temperature  $t_a$  of a controlgear inside a luminaire is very difficult to measure. The measurement of the  $t_c$  temperature is easier and more reliable.

As part of the design process, Tridonic conducts measurements for both  $t_a$  and  $t_c$  and makes sure that both measurements meet the highest requirements. Having a reliable result for  $t_c$  and  $t_a$ , it is possible to provide exact correlations between these two parameters in the product datasheet.

This allows the luminaire manufacturer to determine the expected lifetime of the controlgear based on the  $t_c$  temperature which is easier to measure.

## 6. Position of the $t_c$ point

Typically, the  $t_c$  point is placed directly above temperature and lifetime critical components (e.g. capacitor, coil, etc.). But there is no binding rule for that. The  $t_c$  point is defined by the manufacturer and can be freely chosen. Due to this fact, the  $t_c$  temperature is not suitable to compare different controlgear in terms of their thermal performance.

## 7. Practical use of $t_a$ and $t_c$

For comparison of different controlgear and to get reliable information about their lifetime, the ambient temperature  $t_a$  has to be taken into consideration.

The  $t_c$  temperature is highly dependent on the exact position of the  $t_c$  point and since the manufacturer can define this position, it makes no sense to compare the  $t_c$  temperatures from different manufacturers.

A lower or higher  $t_c$  temperature does not guarantee a better quality or longer lifetime. It could be the result of different manufacturers using different, more or less favourable  $t_c$  points.

Additionally, controlgear from the same manufacturer can have different  $t_c$  temperatures but the same  $t_a$  temperature. Also in that case the  $t_a$  temperature is relevant for the lifetime.

Only the  $t_a$  temperature can provide reliable information about the lifetime of a controlgear.

## 8. Practical examples for $t_a$ and $t_c$ temperatures and their calculation

The following table shows two different Tridonic devices.

Although the  $t_c$  temperatures are different (55 °C and 60 °C), the  $t_a$  temperatures (40 °C) and the lifetime (50.000 hours) are the same.

### Expected life-time:

Type	$t_a$	40 °C	50 °C	60 °
LED Driver type 1	$t_c$	55 °C	65 °C	x
	Life-time	50,000 h	30,000 h	x
LED Driver type 2	$t_c$	60 °C	70 °C	x
	Life-time	50,000 h	30,000 h	x

The LED Driver type 1 has the following data for 50,000 hours lifetime:

\_  $t_a$ : 40 °C

\_  $t_c$ : 55 °C

In the following example the LED Driver type 1 is compared to a device from a different manufacturer which uses a different wording (see following table).

**Operational temperature:**

Specification item	Value	Unit	Condition
$T_a$ -max	50	°C	
$T_c$ -max	90	°C	Maximum temperature measured at $T_c$ -point
$T_c$ -life	80	°C	Measured at $T_c$ -point
Driver lifetime	50,000	h	Measured temperature at $T_c$ -point is $T_c$ -life

The information says:

- \_  $t_a$  (max): +50 °C
- \_  $t_c$  (max): +90 °C

But the  $t_c$  temperature for a lifetime of 50,000 hours is 80 °C which means that for this lifetime the  $t_a$  is not 50 °C but 40 °C.

This means that the comparable values for a lifetime of 50,000 hours are:

- \_  $t_a$ : +40 °C
- \_  $t_c$ : +80 °C

The result shows that the two controlgear types (LED Driver type 1 from Tridonic and the LED Driver from another manufacturer) have different  $t_c$  temperatures (80 °C and 55 °C) but the  $t_a$  temperature (40 °C) and the lifetime (50.000 h) is the same.

So in this case both have the same thermal performance.
